

Integrating BMS and BIM to improve interoperability between simulation and energy management environments

8th AIEE Energy Symposium

Current and Future Challenges to Energy Security

 Building Energy Modeling (BEM) is the process of utilizing a computer to replicate building energy performances.

- BEM predicts building energy consumption, CO2 emissions, peak demands, energy cost and renewable energy production.
- There are two ways to create a BEM:
 - Design the building from scratch within the simulation environment;
 - Use an architectural model.

WHAT IS ENERGY MODELING?

- BIM to BEM is a process that uses BIM to create the simulation input model and usually involves four steps:
 - 1. Simplification;
 - 2. Extraction of data for simulation;
 - 3. Input file creation;
 - 4. Simulation.

Ifc and gbXML as data models and BIM export standards

Federico Rossi Beatrice Maria Toldo, Carlo Zanchetta

- Building Management System (BMS)
 Heating, cooling, ventilation, air conditioning, lighting, etc
 Building Automation Protocols
 rules and standards
- BMS platforms are quite closed systems that use proprietary protocols
- There is a need to use an open protocol to ensure interoperability and integration
- To date, open protocols have been to the series of the ser

• **Problem**: BEM and BMS are mapped according to customised rules and standards

Need for integration between energy simulation (BEM) and real energy data (BMS) to optimize energy behaviour

IFC can act as a communication standard between energy simulations and real energy data

 The application case study presented below was created with the aim of using an IFC file within a BEM and BMS platform in order to compare energy simulation results with actual values.

The experimentation is in collaboration with SMACT Competence Center, one of the 8 Industry 4.0 Competence Centers established in Italy

The case study focuses on a real building located on Via Niccolò Tommaseo, near the Padua Fairgrounds, where Schneider installed multiple devices for smart building control and management.

Federico Rossi Beatrice Maria Toldo, Carlo Zanchetta

The building covers an area of 3000 sqm and is developed over 4 levels.

The building primarily serves two types of use: **production** on the lower levels and **administrative spaces** on the top floor.

The structure is equipped with six AHUs and VRF systems.

Information analysis:

Design drawings for:

- Definition of geometries
- Material characterization
- System schematization

On-site inspection to verify discrepancies in the current state.

Federico Rossi Beatrice Maria Toldo, Carlo Zanchetta

Case study: BIM

Information analysis:

Design drawings for:

- Definition of geometries
- Material characterization
- System schematization

On-site inspection to verify discrepancies in the current state.

• The creation of the information model is the first step to define a digital twin

Architectural model:

Envelope, materials, spaces and zones

Mechanical model: HVAC system

Federico Rossi Beatrice Maria Toldo, Carlo Zanchetta

• The creation of the **IFC** is necessary to integrate BEM and BMS

The process included the definition of the correct MDV for data export

Federico Rossi Beatrice Maria Toldo, Carlo Zanchetta

 Edilclima EC700 is the calculation engine for the energy performance of buildings, including both the monthly method according to UNI/TS 11300 and the hourly dynamic method according to UNI EN ISO 52016-1.

• The software reads the IFC standard for importing the input model

- Information useful for the simulation must be added manually in the analysis software:
 - climate data;
 - envelope data;
 - Temperature and usage profiles of rooms;
 - HVAC and lighting systems.
